Foreword

In response to increasing interest across the international development community in scaling up field-tested models and approaches for addressing widespread and persistent problems, Management Systems International (MSI), with support from the John D. and Catherine T. MacArthur Foundation, published “Scaling Up – From Vision to Large-scale Change, A Management Framework for Practitioners” (the “FRAMEWORK”) in March 2006. The impetus was to address the gap between the numerous successful projects and innovations to be found in the development field, and those precious few that were actually taken to scale.

In MSI’s perspective, scaling up can and should be a systematic process through which promising approaches or models are identified and transferred to new contexts (and often, new organizations) to be implemented on a larger scale.

This document is intended to be a companion document to the FRAMEWORK and includes 15 tools for use with selected tasks outlined in that report. The materials in this document were developed, refined, and applied over a nine year period in 22 projects in India, Mexico, and Nigeria. It integrates several case studies, mostly drawn from the health sector, to demonstrate how the tools are used. The Toolkit is designed as a practical resource for field practitioners.

Acknowledgements

This work has many forerunners including MSI products such as the Institutional Development Framework, the Implementing Policy Change model, and the Logical Framework. It also draws on numerous valuable products from other members of the scaling up community of practice including ExpandNet, the World Bank, IFAD, the Population Fund of India, IFPRI, and the Brookings Institution. Special thanks go out to the MacArthur Foundation for its generous sponsorship of much of the fieldwork on which this product is based, and personal thanks go to Judith Helzner, Poonam Mutterja, and Dipa Nag Chowdhury who believed in and supported this work for over almost a decade.

The principal authors of this document are Larry Cooley, Rajani Ved, and Kate Fehlenberg.

---

1 This FRAMEWORK, revised in December of 2012, is available online at: http://www.msiworldwide.com/files/scalingup-framework.pdf
Chapter 1: Introduction

The **PURPOSE** of this companion volume is to provide a set of tools, guides, and techniques developed and refined through field experience to provide practical help in applying the FRAMEWORK’s conceptual steps and broad tasks. The Toolkit attempts to answer the Critical Questions in Figure 1 and is intended for use by:

- **Field managers** working in development implementing agencies (government or non);
- **Staff and managers at funding agencies** (governments, international donors, and private foundations) interested in scaling up their programs or integrating scaling up into the design of new programs;
- **Academics** in professional fields like public health, public policy, social welfare, international affairs, and international development;
- **Monitoring and evaluation practitioners** interested in integrating scaling up into the design and implementation of their monitoring and evaluation work or in managing the quality of the scaling up process.

**Figure 1. Critical Questions to Ask in Scaling Up**

The **STRUCTURE** of this volume follows the three steps of the FRAMEWORK, and offers tools associated with the 10 tasks referenced in that document. Table 1 below lays out the tools and guides in presented in this volume. Like the FRAMEWORK tasks they support, these tools can be **undertaken in parallel** rather than in a strict linear **sequence**.

Chapter 2: Tools for Framework Step 1: Developing a Scaling Up Plan

Introduction

Figuring out what to scale up often involves tracing backwards from the desirable results we observe to what the project did and how it produced those successful results. Technically, what the project did is called an “intervention”; the term “model” as used here refers to both the intervention and the contextual and operational keys to its success, which are often unarticulated in the original design. Identifying these factors and assessing those which were critical to the success of the intervention is at the heart of identifying the model.

Once available, this information is fed into a Scalability Assessment Tool, which enables a rapid diagnosis of the scalability of the pilot (assessing how easy/difficult scale up may be) and a preliminary identification of the key challenges for getting to scale. Another important part of Step 1 is determining which of the ten scaling methods will be used. Last but not least, Step 1 requires determining who will manage the scale up process, and who will run the scaled up model.

The following tools for Step 1 are to be used primarily with key staff members of the organization that carried out the original “pilot project,” including field staff, and any key external actors with intimate knowledge of the model (e.g., researchers, external consultants involved in the original intervention, members of advisory or steering committees, etc.). The facilitation of this process is best carried out by a third party. As soon as preliminary decisions are taken about the agency expected to implement the model at scale, representatives from that organization should be engaged as well.

1.1: Mapping the Model

These tools help to elucidate key components of the model, the context within which the model was developed, and any evidence of impact, as well as to organize that information. This enables a clearer understanding of the key elements of the model in preparation for subsequent steps, including scalability assessment tasks, the reaching of consensus on which components were critical to the outcomes (and which not), and understanding how best to refine or simplify the model to suit the context of the adopting agency.

Projects that will benefit most from the Mapping the Model tools include those that were not designed with scaling up in mind, but which were nonetheless successful enough to be considered for scale up.
These may include elements of established programs and projects as well as stand-alone pilot projects.

The mapping process makes use of four tools:

- **Tool 1**: Reverse LogFrame
- **Tool 2**: Visual Mapping
- **Tool 3**: Model Profile
- **Tool 4**: Evidence Standards

This section uses the example of a model for the Home-Based Newborn Care pilot to illustrate the first three of these four tools. While this case study is unusual in its level of research and evidence (comparison study design and *Lancet* publication), the process tools can be applied widely.

---

**Example: Home-Based Newborn Care² in India**

**Context**

Society for Education, Action, and Research on Community Health (SEARCH) was set up by Drs. Abhay and Rani Bang in Gadchiroli, one of the poorest and most rural parts of Maharashtra State in India in 1985. Their objective was to address the health needs of remote, underserved populations using community-based solutions. SEARCH set up a hospital and campus whose designs closely resembled the local village structure. SEARCH began to implement a model of community-based research to identify local health needs. One major finding was high rates of neonatal mortality. At the time, nearly 83 percent of newborns in India were born at home and sick newborns were referred to health facilities as standard practice; however, costs and social customs prevented the treatment of newborns in these facilities. During this same time, neonatal mortality was gaining global attention.

**The Model: Home-Based Newborn Care**

The community campus model was implemented as a pilot from 1995-1998 in 100 villages, comprised of 53 intervention and 47 control villages. After obtaining community consent, the initial intervention began to recruit village women with at least a primary education to be trained as Village Health

---

² This example was developed using the references cited below. The case combines features of the original pilot implemented by SEARCH and the Ankur study with the goal of reducing neonatal mortality using the same methodology, but implemented through seven NGOs in the state of Maharashtra.

Workers (VHWs). VHW supervisors were identified (requiring some background in health) and trained in advance of the VHW training. The VHWs were trained for one year using a “step-ladder approach”: classroom training followed by field practice, classroom review, and further training in a new topic. In total, the training consisted of 17 modules delivered through seven training workshops spread over 31 days. The VHWs were trained in home-based neonatal care modules (for common problems such as birth asphyxia, hypothermia, and sepsis). The model expanded in Year 3 to include direct health education interventions for beneficiaries, including pregnant women and mothers-in-law, on pre-natal and neonatal care and danger signs.

The project also developed efficient and extensive patient data systems, which greatly improved data for referrals and health care providers, as well as the documentation of health outcomes. Intensive supervision was a vital component of the pilot: physicians supervised the VHWs, and the study was supported by an external group of neonatologists and practitioners who met once a year at the SEARCH headquarters.

**Evidence: Results from the Pilot**

By the third year of the intervention, about 93 percent of neonates in the intervention area received home-based neonatal care, and neonatal and perinatal mortality rates fell by 62 percent and 71 percent respectively, compared with control villages. The findings of this pilot were published in the *Lancet* and gained wide recognition as a feasible way of reducing infant and child mortality in resource-poor settings across the world.
Tool 1: Reverse LogFrame

Purpose

This tool provides a simple and logical description of the results the model is intended to accomplish and how.

How to Use the Tool

This tool reverse engineers the traditional LogFrame to map out the key goals, outputs, outcomes, and activities of a particular intervention. Based on what the program did, describe its goals and work backwards with the following Guiding Questions:

- What Outcomes were necessary to produce the Goals?
- What Outputs were necessary to produce the Outcomes?
- What Activities were necessary to produce the Outputs?

<table>

VHW: village health worker; MIS: Management Information Systems

....
In addition to this “hierarchy of objectives,” the LogFrame calls for identification of the most important assumptions implicit in the link between activities and outputs, outputs and outcomes, and outcomes and the overall goal, as reflected in the following graphic.

**Figure 2. Linkages**

![Linkages Diagram](image)

Identifying and testing these assumptions (often unstated in project descriptions and implicit in the minds of those carrying out the pilot program) is an essential first step in validating a model’s applicability to new contexts.

**Tool 2: Visual Mapping**

**Purpose**

The visual mapping of the sequence of steps in an intervention—including steps that are contingent on specific conditions—helps to ensure that all key steps are identified and their elements and norms specified.
How to Use This Tool

These graphics, called path diagrams, help to grasp a model’s essence before delving into the detailed requirements associated with each process step in an intervention. There are several sequences that are important in the Home-Based Newborn Care case; one of these, the preparatory or training sequence, is illustrated in Figure 3 below. Visual mapping is a useful exercise to ensure that no component is missed and to better understand issues of sequencing.

Figure 3. Path Diagram for Home-Based Newborn Care Model

![Path Diagram](image)

Tool 3: Model Profile

Purpose

Now that the key objectives and sequences are understood, the elements of the model can be teased out. This mapping exercise includes the identification of the less tangible parts of the model and therefore relies on tapping the tacit knowledge of those involved in implementation. This tool enables the categorizing of key components of the model into its technical and process elements, and also collates information into organizational or social elements. The information in this tool helps participants to reach consensus on the scope—the who and where—of scaling up. It also provides information on which elements could be dropped or modified to simplify or refine the model. Finally, it clarifies the organizational profile and the particular social context in which the model was embedded (the how), as all of these are important in assessing scalability.
How to Use This Tool

Participants in the original project or pilot should be able to provide information on the organization’s vision, mission, values, staffing, funding, human resources, and core competencies. The idea here is not so much an accurate classification of every activity in the correct column, but ensuring that when scaling up decisions are made that decision makers are aware of the multiple components of the model.

The following guide is used to fill in each column:

- **Technical Elements**: This includes technology, human resources, supplies, training modules, salaries, and incentives, etc.
- **Process Elements**: These include program management and strategic design elements such as stakeholder dialogues, community sensitization, training supervision, monitoring, etc.
- **Organizational Profile**: These elements include organizations’ visions and missions, values and culture (rights-based approach, gender equity, or community engagement), levels of collaboration, transparency in decision-making, and governance structures. (Tool 4 can be used as a guide to collecting organizational data.)
- **Context**: This information relates to the physical, economic, cultural, and political environment in which the original model took place. Contextual information is needed to compare the original context to the one being considered for scale-up. This is not to say that a model cannot be scaled to contexts different from the original/pilot context—on the contrary, scaling is often that—but these differences must be understood and managed, especially since some projects’ success may be more a result of contextual rather than technical factors. Two primary types of contextual information are:
  - **Target Population**: Information in this category would include standard demographic data, which is most often available from secondary sources. Examples include: age, gender, education levels, ethnicity, socioeconomic status, and any special characteristics, such as refugee status, religious affiliation, or other salient differentiators should be included here.
  - **Environment**: This refers to both human and physical elements that may have significant influence on the model such as: rural versus urban environments (employment rates, ethnic diversity, family size, etc.); major economic activities (diverse or not, requiring higher levels of education or not, etc.); conflict versus stable environments; local political systems (democratic or authoritarian); and status of infrastructure such as transport and communications systems, etc.

### Tool 3a Guide: Describing the Originating Organization

#### How to Use this Guide

This guide can be used to describe the originating agency (the one that implemented the original model), and then again for the adopting agency/agencies that will run the scaled up model. For the adopting agency, the questions in this guide will identify what is intended to be done. Comparisons between the two descriptions will help highlight differences that may need to be accounted for.

It normally takes several rounds of interviews with various key informants (technical and administrative staff, and leadership) to collect all this information. Questions 1-7 can be answered by technical staff with basic monitoring data and can sometimes be done remotely, while questions 8-13 are more qualitative in nature and require more in-depth discussions with all types of staff, but particularly with the leadership. It is recommended that sufficient time and resources be allocated for...
the collection of this data, and that questions 8-13 be sent in advance to key informants to allow time to prepare for the interview, which should be conducted by a trained interviewer thoroughly versed in scaling up concepts and competent in skilled probing and the elucidation of needed information.

In eliciting and interpreting this information, special attention should be focused on incentives. For sustainable change to occur, it is essential to understand and replicate incentives from the original model or to create an alternative incentive system to reinforce needed actions and desired results. Changes in rules, regulations, and procedures are often necessary and require detailed knowledge of both the originating and adopting organization. For example, many Home-Based Newborn Care programs pay for all transportation and hospital stay costs to encourage mothers to deliver at a clinic. Staff incentives are also critical to ensure the sustainability of new activities post-training.

1. **Type of agency/organization** (check one box)

<table>
<thead>

   Briefly describe the decision-making process (i.e., on whose authority) that enables the scale up of the model or allows others to scale it up (e.g., the CEO, board of directors, management team, donor, etc.). Include any conditions the decision makers may place on allowing others to scale up the model.
Tool 4: Evidence Standards

Purpose

When defining what is the model in Step 1, part of the definition includes an assessment of the evidence of impact, i.e., do we have proof the original model worked? The more credible the evidence, the easier it is to convince policy and decision makers and other stakeholders of the value of the model. This section does not suggest the use of a particular tool, since evaluation methodologies differ significantly and depend on the model being assessed. Rather, the following paragraphs offer a guide to determining the right type of evaluation and considerations for gathering evidence to support the case for scaling up.

Types of Evaluation

It is often the case in scaling up that decision makers in potential adopting organizations are persuaded to adopt a model with less rigorous data if the logic is clear and confirmed by other studies or international evidence. However, experience shows that this strategy can be risky in terms of successful scaling up if assumptions about the external environment are not made explicit, understood, and verified. Also, the process of gathering evidence often reveals previously unknown factors that contributed to the success (or not) of the pilot project.

In order to generate credible evidence and understand the underlying dynamics of a pilot’s success, a range of evaluation methods are possible (see Annex A for Evaluation Method descriptions). While there is a current bias in favor of Randomized Control Trials (RCTs) as being the most rigorous, RCTs are most appropriate for simple interventions with clear and quantifiable results, relatively few components, and a modest number of contextual variables. In addition to generating evidence for the impact of the model itself, a mix of qualitative as well as quantitative data collection and analysis can yield a more comprehensive picture of the economic, political, institutional, and social aspects of the environment in which the model was implemented, and the effects of these various factors on its effectiveness.

Often pilots rely on data collected or analyzed by the organization itself which, even if high-quality, can be perceived as biased. For scaling up purposes, there is a strong preference for a formal external evaluation of the model. A second best alternative is a rigorous external review of internal evaluations.

Types of Data

Statistically significant impact data is preferable, though often not possible. Other types of data (listed below) are more common, though credibility tends to be lower the further down you go on the list, with activity data being the least compelling. In the case of the Home-Based Newborn Care example, this would include:
Impact data: rates of maternal mortality or morbidity, total fertility rates, rate of population growth

Outcome data: percent of institutional deliveries, percent of pregnant women receiving antenatal care

Output data: number of service providers competent to provide emergency obstetric care (EmOC), number of community members with basic knowledge of high risk pregnancies

Activity data: number of service providers trained, community sensitization meetings held

Data from pilot projects are rarely tailored to the information needs, jurisdictions, or decision-making styles of policy makers. Data on effectiveness is often necessary, but usually insufficient. It is critical to make sure the priorities and mandate of the audience you are trying to convince are addressed. For example, giving evidence to the District Health Officer on the success of new training modules is of little use when the training curriculums are set by the Regional Health Board.

1.2: Assessing Feasibility

These tools help to chart the pathway to scale, role of key actors, and likelihood of success. As such, they provide the basis for a detailed scaling up plan.

The assessment process makes use of two tools:

Tool 5: Methods Screen
Tool 6: Scalability Assessment Tool

Tool 5: Methods Screen

Purpose

This tool aids in the identification of an overall scaling up strategy by helping organizations to choose among alternative scaling up methods.

How to Use This Tool

The FRAMEWORK groups scaling up strategies into three approaches—expansion, replication, and collaboration—distinguished from one another by the degree to which the originating organization maintains control over implementation as the model goes to scale.

Expansion here refers to taking a model to scale by increasing the scope of operations of the organization that originally developed and piloted it. This means the model remains with the original implementers, so it is simpler in that administrative and management processes do not need to be re-configured for new adopting agencies. Expansion can take place geographically or in new markets,
such as new target populations (for example, marketing to teens as well as adults) or by product or service (for example, offering a new service within an existing health program).

**Replication** differs from expansion in that the model is taken on by new adopters. This almost always involves significant modifications to the original model to suit the various organizational cultures and capacities of the new adopters, and therefore will require much more attention to identify the salient components of the original model and ensure its integrity (and therefore, effectiveness) is maintained in the transfer. In these cases, an arms-length relationship between the originating and adopting organizations (defined below) usually exists after the transfer.

**Collaboration** falls somewhere between the expansion and replication approaches. Collaboration mechanisms run the gamut from formal partnerships to informal networks and include a number of innovative structures and governance arrangements. Formal partnerships, joint ventures, and strategic alliances are increasingly common methods for organizing collaborative efforts, as are less formal networks and coalitions based on a memorandum of understanding or merely a handshake. Typically, these arrangements include some division of responsibility among the collaborating organizations.

The Methods Screen aids in the selection of the most appropriate scaling up method by comparing the characteristics of the pilot project or model with the pros and cons of each scaling up method.
Each of the three broad approaches to scaling up—expansion, replication, and collaboration—include several alternatives methods. The following table summarizes ten of these methods based on the literature and MSI’s field experience:

### TABLE 4. ALTERNATIVE APPROACHES AND METHODS OF SCALING UP

<table>
<thead>
<tr>
<th>Approach</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expansion</td>
<td>• Growth</td>
</tr>
<tr>
<td></td>
<td>• Restructuring</td>
</tr>
<tr>
<td></td>
<td>• Franchising</td>
</tr>
<tr>
<td></td>
<td>• Spin-Off</td>
</tr>
<tr>
<td>Replication</td>
<td>• Policy Adoption</td>
</tr>
<tr>
<td></td>
<td>• Diffusion</td>
</tr>
<tr>
<td></td>
<td>• Grafting</td>
</tr>
<tr>
<td></td>
<td>• Commercialization</td>
</tr>
<tr>
<td>Collaboration</td>
<td>• Formal Partnerships and Strategic Alliances</td>
</tr>
<tr>
<td></td>
<td>• Networks and Coalitions</td>
</tr>
</tbody>
</table>

Each of these methods has pros, cons, and implications. There are considerations that have yet to be comprehensively catalogued or analyzed, but there is a growing body of case experiences that practitioners can use in choosing among alternative scaling up methods and designing effective strategies.
Tool 6: Scalability Assessment Tool (SAT)

Purpose

The Scalability Assessment Tool (SAT) enables the recognition and differentiation of contextual factors affecting the scalability of a model and the key features that are intrinsic to the model itself. The tool has multiple purposes:

- Helping to decide whether scaling up is a viable option;
- Assessing how relatively hard or easy that process will be; and
- Identifying ways to improve its scalability.

The SAT was originally developed by MSI based on a review of the literature on the diffusion of innovation and scaling up. It subsequently evolved into the present tool of seven sections and 28 questions based on field experience with scaling up in Mexico, Nigeria, and India.

The SAT is divided into the following seven sections and an accompanying score sheet:

1) **Credibility**: The extent to which the model is credible in the eyes of potential adopters, funders, implementers, and other stakeholders, including beneficiaries or end-users. The sources of credibility can take many forms from qualitative, quantitative, and anecdotal evidence to the recommendations of experts or endorsements by prominent people.

2) **Observable**: The extent to which the results (impact or effectiveness) of the model are observable. This is especially significant because most relevant stakeholders and decision makers in the context of scaling up will not be technical experts in the field; for them, seeing is believing.

3) **Relevance**: The extent to which the model is relevant to the concerns of potential adopters, funders, implementers, beneficiaries, and other stakeholders. It is hard to “sell” a new solution when the problem or issue is not considered important. From a scalability perspective, relevance has three dimensions:
   a. There is an objective problem (not just someone’s opinion);
   b. There is a problem from the perception of policy makers or other relevant decision makers; and
   c. There is a problem in the eyes of potential beneficiaries.

4) **Relative Advantage**: The extent to which the model has relative advantages over existing practices. Sometimes this means there are no alternative solutions or responses.

5) **Easy to Adopt**: This refers to the adoption of the model by other organizations as well as its transfer to other social contexts. Scaling up through other organizations depends on the characteristics of the model itself, such as how complex or resource consuming a model is and the capacity of the adopting agency to manage these difficulties. It also involves how the
requirements of the model match up with the culture, capabilities, and incentives of potential large-scale implementers.

6) Testable and Adaptable: The first part of this refers to the ease with which the model can be tried on a small scale by potential adopters without a large commitment of resources. The second part is whether the model can be adapted to new contexts and still retain its effectiveness, even with modifications.

7) Affordable: This criterion refers to the extent to which the model is more cost-effective than existing and competing models. It also includes the extent to which the total cost at scale fits realistically within the resources or financial envelope of possible adopters and funders and the non-financial capacities, especially human resources and infrastructure, available to implement it. This is especially important when considering the scaling of a program that has been largely donor-funded.

The primary purpose of the assessment is not to give a yes or no regarding scaling up but to provide a very rough indication of the scalability of a model and a basis for anticipating the most likely challenges that will be faced.

The SAT is applicable to all three methods of scaling up (expansion, replication, and collaboration); however, specific criteria take on different meanings depending upon which method is being used. A good example is Criteria 8 in the SAT: “[Does the model] address an issue that is currently a high policy priority?” In the case of expansion, the priority would be that of concern to senior decision makers in the piloting organization, most likely the Executive Director or a board of directors. In the case of replication, the priority would be that of key decision makers in the adopting organizations; and in the case of collaboration, it would be key decision makers in each of the collaborating organizations.

How to Use This Tool

What is Needed Before You Get Started?
Using the scalability tool requires:
- An understanding of the model itself and the context in which it has been effective
- An understanding of any evidence of efficacy, efficiency, or both
- A basic understanding of the potential adopting institutions and infrastructures in place, and their capacities and capabilities
- An understanding of relevant policy, budget, and resource issues in that sector

Scoring
Once the SAT has been reviewed and the explanation of all the indictors is clear (see Annex for Scalability Assessment Tool Terms), the checklist is scored by simply putting a check mark or X in the appropriate column for each criterion. The scores in each of the three columns are added to provide a crude assessment of scalability. The user(s) can then look at criteria where the intervention was scored as making scaling up more difficult and assess how critical this complicating factor is to scaling up,
and what can be done to address it. For example, if the model lacks cost data, what can be done to generate cost data? If the model appears to be expensive relative to resources available, what can be done to make it less expensive to implement? In areas where information is not available, such as on the cost envelope, flagging the need to do research on this issue should be added to the list of actions to take.

**Case Study: SAT and the PRACHAR Project, India**

The Packard Foundation funded Pathfinder International/India to design and field test a pilot model at small scale titled PRACHAR (Promoting Change in Reproductive Behavior) whose goal was to increase the age of women at first conception and promote child spacing. The design was a combination of training, behavioral change communications, and service delivery activities designed to bring about significant changes in the knowledge, attitudes, and behavior regarding these issues.

PRACHAR was implemented in two phases in five districts in Bihar: PRACHAR I was implemented from July 2001 to May 2005 and was designed to see if the basic approach—a comprehensive, community-based education program—would produce the expected results, increasing the age of first conception and child spacing. PRACHAR II (2005-2009) was designed as an operations research model to answer the following scaling up questions: (a) whether a simplified model would be as effective as PRACHAR I; (b) how the length of implementation affected results; and (c) whether the results would persist after active intervention had ended. Following these two phases, MSI was asked by the Packard Foundation to assess the scalability of the PRACHAR model.

MSI applied the SAT to the original PRACHAR model as tested in Phase I, and then revised its assessment based on the Phase II results. For the 28 items contained in the tool, eight scored as making scaling up easier, 9 scored as making scaling up more difficult, and eleven were neutral. MSI found that the models (the original in Phase I and the refined one in Phase II) had a number of notable strengths, especially the strong evidence for success and the fact that it presented a solution to an objectively important public health problem in the absence of existing alternatives. MSI found that the Phase I model also had a number of characteristics that would likely make scaling up challenging, the most important of which was that the original model was complex and process intensive.

| Recommendation | Develop cost data on the PRACHAR model and different versions tested under PRACHAR II, and cost-benefits of simpler versus more complex models |
Chapter 3: Tools for Framework Step 2: Establishing the Pre-Conditions for Scaling Up

Introduction

The tools in this section involve the most neglected yet critical part of the scaling up process: securing the support needed to go to scale, and to stay at scale. This set of tools is most useful in supporting Step 2 of the FRAMEWORK. The result of Step 2 is that decisions for scaling up are taken and resources (financial and human) for scaling up are allocated.

2.1: Mobilizing Support

The tasks of legitimizing change and building a constituency require an understanding of the policy milieu and the key stakeholders involved in the (potential) scaling up process. Legitimation implies placing the need for change high on the agenda of decision makers. It involves the emergence or designation of one or more policy "champions" with credibility, and the willingness to use that political capital in support of the model. Constituency building is the identification, assembly, and mobilization of coalitions necessary to ensure the adoption and implementation of needed changes.

All of this requires analyses of potential supporters and opponents and their interests, resources, and willingness to be involved. Conducting such analysis is facilitated by the use of four tools:

- **Tool 7:** Stakeholder Analysis enables a listing and analysis of stakeholders and an understanding of their positions and resources
- **Tool 8:** Network Mapping enables the charting of decision-making processes and the people and groups who can influence each of these processes
Tool 9: Force Field Analysis helps to array and assess the forces supporting or opposing a certain change

Tools 10 & 11: Advocacy Strategy Profile (Parts I and II) enables proponents to assess how best to engage government agencies in support of the scaling up effort

While these tools can be used in conjunction with one another to provide a fuller picture of scaling up prospects and strategies, it is more common for organizations to select one or two of these tools based on their skills and circumstances.

Tool 7: Stakeholder Analysis

Purpose

The purpose of a stakeholder analysis is to inform the process of constituency building by identifying and examining potential sources of support and opposition for the scaling up of a particular model. It is a tabular presentation of key stakeholders in relation to their interests, positions, and resources relevant to that policy. Stakeholder analysis is useful during the formulation of the scaling up strategy and when the model is being implemented at scale. At the formulation stage, it helps to ensure that policies are shaped in ways that support the adoption and scaling of the model. During the implementation stage, the tool helps to build an appreciation of the relative importance of different groups and the roles each may play in the implementation process, allowing for early engagement and wider ownership around the model and enhancing its chances of success and sustainability at scale.

The definition of stakeholder is an individual, group, or organization

- Whose interests are affected by the model/issue/policy
- Who has an ability to impact the model/issue/policy
- Who has an interest (stated/unstated) or stake in the model/issue/policy
- Who will “win” or “lose” when the status quo changes

The key uses of the stakeholder analysis are to:

- Enable an assessment of the sources of influence, positive or negative, these groups will have
- Identify critical issues around which conflict and compromise are possible
- Help develop strategies for legitimation and advocacy for scaling up
- Identify resources for advocacy and for implementing at scale. This involves strategies for activating constituencies located in cell 1 in Figure 5 below; strategies for enhancing the influence of constituencies in cell 2; and strategies for appealing to stakeholders in cell 3.
How to Use the Tool

The stakeholder analysis is presented in a tabular format with five columns and as many rows as there are relevant stakeholders.

TABLE 5. TOOL 7 STAKEHOLDER ANALYSIS TABLE

<table>
<thead>
<tr>
<th>GROUP</th>
<th>GROUP’S INTEREST IN ISSUE</th>
<th>RESOURCES AVAILABLE</th>
<th>RESOURCE MOBILIZATION CAPACITY</th>
<th>POSITION ON ISSUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of group</td>
<td>- Estimate the level of group interest in the issue (e.g., high to low) - Indicate what those interests are (political, financial, etc.)</td>
<td>- Summary of resources held by the group or to which it has access (may include economic, information, status, legitimacy, power)</td>
<td>- Estimate of how easily the group can mobilize resources in pursuit of objectives (high or low)</td>
<td>- Estimate of the group’s position on the issue (e.g., pro or con or positive to negative, as ranked on a scale of +3 (very supportive) to -3 (very opposed); 0 is neutral</td>
</tr>
</tbody>
</table>
Column 1 (Group) presents a list of relevant stakeholders. Although a full listing of stakeholders would include any person or group affected by or able to affect the scaling up of the model, for purposes of this analysis, stakeholders are considered relevant if and only if the group or actor has significant mobilizable resources that can be applied for or against the scaling up of the model. The best way to develop a first draft of this list is usually in a brainstorming session with six to ten knowledgeable practitioners. This is often referred to as a stakeholder consultation. It is not unusual for such brainstorming sessions to identify 20 or 30 significant stakeholders. This preliminary list should be edited and used as a point of departure for the analysis.

Column 2 (Group's Interest in Issue) lists those interests that will be affected by the scaling up of the model. What are the group’s specific interests that would be affected positively or negatively? These questions are best answered by either engaging these groups in a dialogue or by putting yourself in their shoes.

Column 3 (Resources) identifies resources that the group possesses that could be brought to bear in the decision-making or scaling up of the model. Can the group offer some special knowledge or information? Would the group’s status or presence on one side of the issue heavily influence its implementation or blockage?

Types of resources can be classified as follows:
- Economic: financial, human (expertise), or in-kind resources such as media time.
- Information: knowledge gained through study, communication, research, or instructions; or facts, data, analyses, and studies.
- Status: a position or rank in relation to others, personal renown, or reputation that can influence decision-making.
- Power: the ability to compel behavior from persons or organizations.

Column 4 (Resource Mobilization Capacity) describes the ease and speed with which the group can mobilize and deploy its resources. If the group cannot mobilize or make effective use of its resources, then they are not really resources in any meaningful sense of the word.

Column 5 (Position on Issue) characterizes the group’s position regarding the issue. It should give an indication of the strength of the group’s opposition or support (for example, using a -3 to +3 scale).

The example below provides a summary of a completed stakeholder analysis and the strategic implications drawn from it.

<table>
<thead>
<tr>
<th>List of Stakeholders</th>

TABLE 6. STAKEHOLDER ANALYSIS: POLICY ON EXPANDED INSURANCE COVERAGE FOR HIV/AIDS
### Alternative Strategies Suggested:

- Begin with stakeholders possessing the strongest support (+3), then move to engage the next concentric circle of supporters, etc.
- Bring in the insurance companies early as they will be the ultimate owners and managers of this effort.
- Begin at the top: Presidential Initiatives or big tent efforts with high visibility and high-level political support.
- Look for people who are able to bridge with other groups and concentric circles based on the nature of the group (i.e., in both camps) and/or personal/collateral relationships.
- Work with or involve like-minded legislators or legislative staff.
- Divide stakeholders into those with high support (but minimal resources) and those with high resources (but minimal support); use the first group to articulate strategies and then strategize about how to reach out to the second group in terms of interests.

Tool 8: Network Mapping

Purpose

A network map is an analytical tool used to mobilize support for and against specific decisions. Its key uses are:

- Mapping the decision-making process or flow and identifying who the decision makers at each step
- Identifying entry points and potential ways of gaining access to the decision-making process
- Augmenting a stakeholder analysis

How to Use This Tool

There are several steps in developing a policy network map. Below are some guiding questions and considerations:

- What are the different points through which a funding decision or policy passes?
- Precisely what formal decisions need to be made for scaling up of the model (policy, regulation, law, legislation, etc.)?
- Who are the decision makers (policy makers, political leaders)? Who are the actor(s) in charge of each step?
- In what ways can officials exercise influence over this process? Do they have any particular skills or contacts that might help in this process?
- Are there other actors, though not officially part of the processes, who have substantial influence over key decision makers?
This information is then displayed graphically, as in the following example, as a basis for serious discussions of advocacy strategies and messages.

Figure 6 below presents a network map for a fictional country seeking to scale up new methods of extending health care services to poor, rural workers and their families. The map suggests that important constituents of the president include the health workers union and the medical association. Perhaps these groups could be brought into some kind of alliance that could bring pressure to bear on the president? Within Congress, it seems that the committees on budget and finance are in charge of approving the budget submitted by the president. Might there be some mechanism to influence the committee or the committee staff charged with the preparation of authorization bills for the budget? Does a certain member of the committee have a keen interest in the problems of rural health? Perhaps the minister could bolster member interest with pertinent and timely information that could be used to defend the policy in committee debates or hearings. Perhaps pressure from diverse groups like the Mayors’ Association, the National Cooperative Association, and the Agricultural Workers Union might be brought to bear because while these groups are not direct players in the policy process, they are the eventual stakeholders and could be important sources of influence.

Figure 6. Network Map, Health Sector of Boliguay
Tool 9: Force Field Analysis

Purpose

Force Field Analysis is another convenient method to illustrate the forces that oppose or support scaling up a particular model. Force Field Analysis enables critical assessment of which force(s) hold the key to changing the status quo. The network map and the Force Field Analysis are usually developed independently and often only one or the other is needed.

How to Use This Tool

On one side of the chart are arrayed the forces supporting the decision to scale up the model. These are called “driving forces” and can be economic, political, cultural, environmental, or technological (e.g., the upcoming election, recent protests, rising disposable income, support from the medical association, etc.). The forces opposing change are called “restraining forces” and can likewise be economic, political, cultural, environmental or technological (e.g., competing budget priorities, opposition from competing service providers, lack of convincing evidence, bureaucratic inertia, etc.).

Another way to think of these forces is in terms of incentives and disincentives. By definition, things are the way they are because driving and restraining forces balance each other. To advance a model, the forces favoring change need to be stronger than those that oppose it; this can happen either by adding new driving forces or by disabling current restraining forces. Extensive experience and strong theory demonstrate that the better strategy is usually to find ways of disabling or reducing current restraining forces because new driving forces tend to create new opposition.

Given below is the application of Force Field Analysis for a model to train primary care physicians in emergency obstetric care (EmOC) where specialist Ob-Gyns physicians are not available.

Case Study: FOGSI (Federation of Obstetric and Gynecological Societies of India)

Maternal mortality in India remains high partly because of limited access to EmOC. In most parts of rural India, EmOC is not available due to the shortage of trained medical and paramedical staff, with few obstetricians and gynecologists in most districts. Most general practitioners in India do not provide even basic EmOC. Baseline assessments conducted by the Averting Maternal Death and Disability Program of the Mailman School of Public Health of Columbia University in rural Rajasthan and Maharashtra showed that EmOC was only available 10-15 percent of the time in some districts.

Model Description

In 2003, the MacArthur Foundation supported the FOGSI Societies of India through technical assistance from the Johns Hopkins Institute for Gynecology and Obstetrics (JHPIEGO) to develop the capacity of general practitioners and non-specialist doctors to provide quality EmOC services.

---

4 Established in 1950, FOGSI is a federation of more than 184 individual city and state-based societies of obstetricians and gynecologists throughout India.
Although there were no outcome data for the success of the model, it was widely acclaimed in policy circles as an effective approach to reducing maternal mortality. In 2006, the Government of India, impressed by the potential of the model and seeking to expand its human resources to manage obstetric complications, particularly in the rural areas, committed Rs. 20,000,000 (USD 5 million) to establish training sites in 25 centers across the country. However, since obstetricians and gynecologists have traditionally blocked the shifting of EmOC skills to non-specialist physicians, legitimizing this key component of the model was a significant challenge.

A Force Field Analysis helped to identify the factors that supported and restrained the scaling up of this change and aided in developing an effective scaling up strategy. A portion of that analysis is shown below:

<table>

</tr>
</tbody>
</table>

**Tool 10: Advocacy Strategy Profile – Part I**

A major element of taking any intervention to scale is advocacy. A wide range of stakeholders need to be persuaded that the model proposed for scaling up is sufficiently better than the status quo and other available alternatives to justify the time, costs, and efforts needed to make the change.

If new resources are required, those in charge of funding decisions need to be persuaded to mobilize the necessary resources and perhaps to re-direct them from another use. If organizations need to re-purpose, take on new responsibilities, or to discontinue old ones, the leaders of those organizations need to be convinced that these difficult and taxing changes will be worthwhile.

Who performs these advocacy functions and what guidelines can we offer them? In some countries and sectors, there are a host of organizations whose explicit purpose is advocacy. Often, however, these advocacy functions are performed by organizations that play other roles as well—service delivery organizations, professional associations, foundations, civic organizations, think tanks, private companies, and government policy units. In addition to these third party institutions, advocacy functions are often performed by the originating organization (i.e., the organization that developed the model), adopting organization (i.e., an organization that hopes to apply it at scale), or intermediary organization (i.e., an organization helping to facilitate the scaling up process). The following tools and guidelines are intended for people within any of these organizations charged with advocating for the scaling up of innovative models.

**Purpose**

The Advocacy Strategy Profile is a decision-support tool that helps advocates choose the best
approach for constructively engaging with the government based on the realities of the political and administrative environment, the resources available to them, and their core competencies.

**How to Use This Tool**

The profile distinguishes five different advocacy approaches that make up an advocacy strategy continuum (see below). At one end of the continuum are approaches based on full collaboration with the government and limited to a specific initiative. At the other end of the continuum are permanent advocacy groups dedicated entirely to lobbying government on behalf of members’ concerns and interests.

**Figure 7. Advocacy Strategy Continuum**

<td>- Use of multiple tactics</td>
</tr>
</tbody>
</table>

To determine the advocacy approach most appropriate for a given organization, the leadership of the (potential) advocacy group begins by completing the Advocacy Strategy Profile: Part I below, characterizing the prevailing situation with regard to each of the 11 factors on the grid and placing an “X” in the appropriate box on the grid. The numbers 1 and 5 are defined by the narrative statements at either side of the grid. Numbers 2, 3 and 4 reflect a range of intermediate positions. If those preparing the profile differ in their views regarding the proper rating of a given factor, they should discuss the issue until they reach agreement or, if that fails, combine their ratings into an average.

</tr>
</tbody>
</table>

After scores have been agreed upon for each factor, a line is drawn connecting the “X’s.” In general, the placement of the line from left to right corresponds with the five advocacy approaches indicated in the advocacy strategy continuum figure on page 44 above. For example, if the line is to the far left, the suggested approach would be collaborative. Often, however, the line connecting the “X’s” is not a straight one. Under these conditions, the profile should be used as the basis for an active discussion within the organization about the opportunities and risks associated with different advocacy models and whether it is possible to move some factors from the left to the right on the profile.
Tool 11: Advocacy Strategy Profile - Part II

Purpose

Regardless of structure and approach, effective advocacy organizations need to perform certain functions. Part II of the Advocacy Strategy Profile helps members of those organizations and third parties to determine where specifically organizations are most in need of strengthening. This can be done in the form of a list of strategic actions (see figure below), each of which can be scored from 1 (no action yet taken) to 5 (fully effective). Intermediate ratings necessarily involve subjectivity on the part of those doing the ratings. Items scoring 2 or less are candidates for attention as the organization seeks to deepen the effectiveness of its lobbying and advocacy efforts.

### TABLE 8. TOOL 11 ADVOCACY STRATEGY PROFILE, PART II

<td></td>
</tr>
</tbody>
</table>
Joint meetings held to examine mutual interests and negotiate terms of joint actions, responsibilities of each partner and to examine needs for acquiring other resources (e.g., collaboration of think tanks, international organizations).

Coalition, alliance, network formed with clear understanding of each partner’s role. Position statements and supporting presentation materials developed. Strategy for coalition activity developed and resources identified for carrying out actions.

Joint actions planned and executed, including the development of public forums, lobbying, media campaigns, etc.

**Advocacy group implements strategy for issue advocacy:**

- Press releases, public forums held, participation on local talk shows, etc.
- Policy papers disseminated.
- Members initiate direct action to become “opinion leaders” on issue.
- Lobbying campaign initiated and sustained.
- Group develops scorecard on actions taken and results achieved.
2.2 Mobilizing Resources

The task of **realigning and mobilizing resources** requires a nuanced understanding of the one-time costs associated with the scaling up process and the unit costs of operating the model at scale. These costs need to be disaggregated by source (i.e., who is expected to incur what costs) and linked where appropriate to offsetting revenues; or new revenues need to be identified for each cost. The model’s costs also need to be compared with that of competing models, and the one-time start-up costs of transferring the pilot to a new organization need to be estimated provided for. A tool to aid in the identification, analysis, and presentation of this cost information is the *Scaling Up Cost Analysis Manual* developed by Population Foundation of India, MSI’s collaborating partner in India.5

**Tool 12: Cost Analysis Manual**

The cost analysis manual, which does not presume previous training in economics or accounting, provides guidance to program managers on (1) how to apply costing techniques to estimate resource needs for an intervention, and (2) how to do a simple analysis of cost-effectiveness to assess the value for money invested in a particular intervention. The concepts and techniques presented in this manual are explicitly linked to the decisions, steps, and tasks associated with scaling up.

The manual presents the basic concepts and classifications related to costs and cost estimation before proceeding to lay out a step-by-step process for cost analysis. It then details a means for assessing and analyzing incremental costs or changes to unit costs associated with scaling up particular initiatives, including guidelines (summarized below) for estimating these costs. The manual also presents a simple procedure for cost-effectiveness analysis.

**TABLE 9. GUIDELINES FOR ESTIMATING EFFECT OF SCALING UP ON UNIT COSTS**

</tbody>
</table>
Chapter 4: Tools for Framework Step 3: Managing the Scaling Up Process

Introduction

This set of tools is most useful in supporting Step 3 of the FRAMEWORK. The desired result of Step 3 is the sustainable application of the new model at scale. The three tasks of Step 3 are:

- Modifying and Strengthening Organizations
- Coordinating Action
- Tracking Performance and Maintaining Momentum

The section presents one tool to assist with each of these tasks. These tools are:

Tool 13: Institutional Development Framework: Provides a basis for planning and tracking needed changes in the adopting organization(s)

Tool 14: Organizational Responsibility Chart: Helps to coordinate the actions of all parties involved in the scaling up process

Tool 15: Monitoring and Evaluation Guidelines: Provides a basis for keeping the scaling up process on track and to assess performance at scale

Tool 13: Institutional Development Framework

Purpose

The purpose of the Institutional Development Framework (IDF) and its associated tools is to help an organization scale up its operations, align with new policy directions, increase efficiency, and chart its own path to institutional development. One of the most appealing features of the IDF is its ability to

---

track progress over time and illustrate graphically to all concerned how effectively the organization is implementing its proposed changes. The IDF can be used to assess an organization before or during scaling up to plan and track necessary changes in the adopting organization. It does this by helping an organization to: (1) consider what it will take to make it successful; (2) assess its own strengths and weaknesses in light of those factors, (3) map a prioritized plan for improvement; and (4) measure progress against the goals it sets. The framework is based on empirical studies in several countries and is reasonably free of a regional or cultural bias.

**How to Use the Tool**

The most effective way to use this tool is to develop it in a workshop setting with representatives from the originating organization, adopting organization, and other key stakeholders. While there is no one “right” answer, the interplay between these individuals is virtually assured to generate important insights about the changes needed in the adopting organization and the best way to encourage these changes.

The IDF is organized in a matrix format. In the first column are listed the institutional “resources” critical to an organization’s effectiveness. The untailed (generic) version of the framework includes five such resources, each of which has several components (see table below). Listed across the top of the matrix are the four stages through which organizations mature.
### TABLE 10. INSTITUTIONAL DEVELOPMENT FRAMEWORK

<table>
<thead>

<tr>
<td>External Resources</td>
<td></td>
</tr>
<tr>
<td>- public relations</td>
<td></td>
</tr>
<tr>
<td>- ability to work with local communities and governments, etc.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 1: Adapt Generic IDF**

The organization reviews the generic framework (ideally, with a facilitator) first to modify the categories and components to reflect their particular circumstances and second to identify, for each cell of the matrix, one or more performance criteria. The questions driving this process should probe what it will take, organizationally, for the institution to effectively implement the new model as scale. A sample truncated IDF is presented below:
### TABLE 11. TOOL 13 CRITERIA FOR PROGRESSIVE STAGES IN THE IDF

<table>
<thead>
<tr>

<tr>
<td></td>
<td>Staff provide technical input only</td>
</tr>
<tr>
<td>Management Systems</td>
<td>No formal file system exists</td>
</tr>
<tr>
<td></td>
<td>Few administrative procedures formalized</td>
</tr>
</tbody>
</table>

### Step 2: Plot the Organization on the IDF

The IDF is based on “Progress Cells” which correspond to the following four stages through which organizations generally change or evolve:

\[
\text{Start-up} \rightarrow \text{Development} \rightarrow \text{Expansion/Consolidation} \rightarrow \text{Sustainability}
\]

The next step is for the organization to examine the IDF, row by row, and determine where along the continuum it is currently situated. The simplest approach is to mark an “X” in the spot that describes the organization at the time of the assessment (see matrix below).

Although the cells of the IDF reflect benchmarked best practices and progression sequences, users of the tool are encouraged to amend the “Progress Cells” to ensure they capture where the organization is currently “located,” and where it needs to be to operate the new model effectively at scale.
Step 3: Set Institutional Development Priorities, Goals, and Improvement Strategy

The next step for the organization is to determine which components are most important for the successful implementation of the scaling up effort. Having identified the areas that need change or improvement, the organization can set goals (e.g., moving from a “1” to a “3” in its financial management systems) and a timeframe (e.g., three months, six months, or one year) to accomplish each goal. In most cases, organizations will select only a few areas (rows) on which to concentrate their efforts as resources allow. It should be noted that timeframes will depend on both the sequencing of the changes associated with the scaling up the model and the demands and resources of other actors in the scaling effort.

Tool 14: Organizational Responsibility Chart (ORC)

Purpose

The purpose of the Organizational Responsibility Chart (ORC) is to disentangle the respective roles of the individuals and groups responsible for scaling up the model. It is particularly useful when activities depend on a number of different organizations or organizational units (e.g., different departments/divisions or levels, such as national, regional, local, etc.). In a simple matrix, the ORC displays the responsibilities of each major actor with regard to each significant task. It can and should be used not only to describe current practices, but also to guide streamlining and other organizational improvements required for implementing the new model. It can be used in conjunction with the IDF—once key capacities or improvements have been identified, the ORC can help facilitate their achievement—or as a separate tool for multiple organizations that are involved in taking a model to scale.

The rows of the matrix correspond to the major activities needed in the scaling up effort. These activities should be listed in the first column of the matrix, grouped by major output or category of activity. Normally, a participatory planning workshop (ideally facilitated by the intermediary organization) is the best way to develop this list and to ensure that all key actors agree on it. In some cases, it is also appropriate to use this same list as a starting point for developing a bar chart, PERT chart, or schedule of deliverables.7

---

7 A PERT chart is a project management tool used to schedule, organize, and coordinate tasks within a project. PERT stands for Program Evaluation Review Technique. A similar methodology, the Critical Path Method (CPM), has become synonymous with PERT so that the technique is known by any variation on the names: PERT, CPM, or PERT/CPM. For additional information search for PERT in www.whatis.com.
The other columns of the matrix correspond to the full range of actors (individuals, organizations, and/or organizational units) involved in scaling up the model. By excluding minor players, it is usually possible to limit this list to somewhere between 10 and 20 major actors.

For each of the listed activities, four questions are asked:

1. Who (if anyone) must agree to or approve this activity?
2. Who is responsible for executing this activity?
3. Who should provide tangible support for this activity?
4. Who needs to be kept informed about this activity?

If someone or some group has approval authority for a given activity, the letter “A” should be written in the corresponding box in the matrix. For those responsible for executing the activity (i.e., those that could be held responsible for its successful completion), write an “R.” Those providing support receive an “S,” and those to be informed receive an “I.”

While an ORC may be completed by one or more analysts, it is most effective when used interactively by directly affected parties to clarify and streamline working relationships. One very useful technique is to have the key actors complete the chart separately and then compare their versions as a starting point to negotiate an agreed version. The following questions and guidelines can be used to inform that discussion:

- Are there major disagreements or differences of opinion about the list of key activities or allocation of responsibilities?
- Are there important activities with too many people (or no one) in change?
- Are there apparent bottlenecks (i.e., do the same people have too many things to do)?
- Do agreed procedures exist for making decisions when there is more than one decision-maker? For supervising activities that cross organizational lines, and for sharing information with those who need it?

The first rule of coordination should be to eliminate the need for coordination wherever possible and, where needed, to opt for the simplest approaches possible. For this purpose, it is worth noting that sharing information is normally easier than sharing resources, and sharing resources is normally easier than joint action. Seen in the context of the ORC, this suggests that it is usually more efficient for cells of the matrix to be empty than to be filled. This needs to be balanced, however, by the dictates of the particular task and by the requirements for transparency and democratic decision-making.

A=Approves  R=Responsible  S=Supports  I=To Be Informed

One of the most attractive features of ORCs is the speed with which an individual or group can learn the tool and put it to practical use. Although this can be done using written guidance alone, it is helpful to have someone experienced in the use of the tool spend time (usually 30 minutes is sufficient) introducing it and answering questions. When used in a workshop setting, it is very helpful to have the benefit of a trained facilitator who can help the group see potential coordination problems and resolve any conflicts that may arise with regard to roles and responsibilities.
Tool 15: Monitoring and Evaluation Guidelines

Purpose

It is essential to monitor and report on both the scaling up process (getting there) and implementation at scale (once you are there). The monitoring and reporting process can and should be used as part of an ongoing strategy to maintain political and popular support and funding. While ongoing monitoring is integral across each step, it is particularly important to track the effects of introducing a new model and to make adjustments if results differ from what was intended. Such monitoring and evaluation ideally begins early in the process, with assessments during Step 1 to determine the effectiveness of the pilot project (Tool 4). In addition to the usual requirements for sound project management and donor reporting, such studies need to anticipate the questions and concerns of the broader audience involved in approving, funding, and implementing the scaling up process. This puts a particular premium on monitoring and evaluation being done in a credible, public, and transparent manner, and there is considerable value to involving independent third parties in this effort.

In sum, there are three main ways in which monitoring and evaluation tools are used to support a scaling up process:

1. Evaluation of the Model (see Tool 4, Evidence Standards)
2. Monitoring the Scaling up Process
3. Monitoring and Evaluating Performance and Impact at Scale

How to Use This Tool

Guide: Monitoring the Scaling Up Process

In contrast to rigorous evaluations on the impact of a model, monitoring the progress of a scaling up plan relies more on setting concrete performance indicators and milestones, and using well-established but useful tools such as work-plans, GANTT charts, performance monitoring plans, and Microsoft Project Manager to track and report progress against schedules, milestones, and products associated with each task. Numerous published guidelines exist for the application of these tools. The reverse LogFrame (Tool 1) is an excellent place to begin developing these indicators and monitoring systems.

In addition to efforts to track the roll-out of the model, it is important during the scaling up period to monitor the continual commitment of those who fund and implement interventions at scale; this may also be thought of as “sustainability” or an “end game.” Monitoring of this type is often closely linked to advocacy activities and is meant to take place in the public eye. This aspect of monitoring is sometimes carried out by a “watchdog” or citizen committee and can often be integrated into oversight and ongoing efforts to build a constituency for change. For this type of monitoring, specific tools are less important than consistency of attention and willingness of the monitor(s) to sound an
alarm when progress stalls, the attention of implementers begins to drift, or the intended change is watered down.

Also of critical importance is the creation of avenues for feeding this information back to the public and to decision makers, and ensuring that it is widely discussed. The press, academia, and non-partisan monitoring organizations can play important roles in this process. Among other things, this monitoring is a catalyst for maintaining momentum and accountability, following the adage “what gets monitored gets done.”

Suggested mechanisms for this kind of oversight include:
- Citizen oversight panels
- Public hearings
- Blue-ribbon panels
- International monitoring groups
- Listserves and other web-based, open-access dissemination
- Comparative scorecards
- Sustained media coverage

**Guide: Monitoring and Evaluating Performance and Impact at Scale**

Evaluation at scale can serve two purposes: (1) to reconfirm expectations about differences in the effectiveness of a model in diverse cultural settings; and (2) to examine situations in which the model at scale is over- or under-performing, and to determine why. As this suggests, the types of evaluations that will be appropriate when an intervention has been taken to scale will likely vary widely depending on the intervention. Monitoring the fidelity to the original model (or a simplified version of it) will likely be needed with most scaling up initiatives.

Once the scaled up model begins to produce results, both monitoring of outcomes and evaluation of impact will be required as with any other program. If the adopting agency is part of the government or is cooperating with the government, monitoring data should be captured by, or delivered to, a management information system that is congruent with existing national systems. The indicators for this phase of the process should include parameters for monitoring quality as well as quantity.

The term **implementation fidelity** is used to capture the notion of compliance guidelines for delivering an intervention at scale. Useful products are emerging to help those involved in scaling up efforts conceptualize and measure implementation fidelity (for example, see [http://www.nrcld.org/rti_manual/pages/RTIManualSection4.pdf](http://www.nrcld.org/rti_manual/pages/RTIManualSection4.pdf)), and a set of helpful process questions is provided below.
## Table 14. Guiding Questions for Process Monitoring

Chapter 5: Conclusion

This Toolkit is intended as a living document. As experience grows, we expect the number of tools, and the tools themselves, to evolve and deepen. We plan to update in real time the FRAMEWORK document, Toolkit, and the cases on which they draw and to re-issue revised versions of these documents periodically. If you make yourselves known to us, we will make sure this information finds its way to you.

For the sake of clarity, the cases on which this document is based are drawn from the health sector. The FRAMEWORK and various tools have also been applied in fields as diverse as food security, livelihoods, local government, early childhood education, judicial sector reform, and community policing. We hope the variety of these applications will continue, and we are committed to doing whatever we can to document and support that expansion.

There is a vibrant and growing community of practice around issues associated with scaling up, and we expect the continual growth of that group and its insights. To that end, we invite interested practitioners and researchers to contribute their experiences, and their reactions to this document, to: www.scalingup@msi-inc.com.
Annex A: Types of Evaluations

The impact of a program is essentially the difference between beneficiary outcomes after program implementation (treated outcomes) and what the outcomes would have been had the program not happened (counterfactual outcomes). The main impact evaluation problem is that while treated outcomes are observed, counterfactual outcomes are not. To measure program impacts, researchers use a variety of rigorous techniques to determine counterfactual outcomes. The methods fall into two general categories, which are discussed below: randomized control trial (RCT) evaluations and quasi-experimental evaluations.

Randomized Control Trials (RCTs)

RCT evaluations employ the most rigorous logic, structure, and procedures available for detecting and quantifying program impacts. They are distinguished by two key features: (1) the evaluation design and methodology are developed prior to program implementation, and (2) the design includes a formal counterfactual that permits a valid comparison of program results for beneficiaries to outcomes experienced by comparable groups not affected by the program.

Planning an impact evaluation during the program’s development stage makes it possible to arrange for the collection of baseline measures for key data elements prior to the program’s initiation. These efforts may include new surveys or other data collection specifically aimed at establishing the baseline for measures of interest. To establish credible counterfactual conditions, RCT evaluations employ rigorous experimental designs—including random assignment of individuals, families, communities, or other aggregates—to treatment and control groups to ensure comparability of the populations.

The solution to an impact evaluation challenge is straightforward under a RCT design, where random assignment is used to determine which units (households, geographic areas, etc.) will receive the treatment.

To estimate program impacts in an RCT design, two sources of data are required:

- **Baseline participant information**: The evaluator must collect information about the units (households, individuals, etc.) assigned to the treatment or control group at the time as the random assignment (that is, before the implementation of the program). This information may include participant contact information; key socioeconomic characteristics; employment, health, and nutrition status; and household information. This information may be available from data already collected by the country’s statistical agencies. Otherwise, data must be collected through a population-based survey.
Follow-up data: The evaluator must collect information on participant outcomes (e.g., employment, wages, nutrition, health, etc.) following implementation of the program. This information may be collected from existing data sources or through follow-up surveys.

Random assignment ensures that treatment units are equivalent to control group units in their observed and unobserved characteristics; thus, any subsequent differences between treatment and control outcomes can be attributed to the program. This explains why RCT designs are preferable for rigorously assessing program impacts relative to other methods that rely on statistical methods to identify appropriate comparison groups.

Since random assignment is used to determine program participation, we can estimate program impacts through treatment/control group comparisons of mean outcomes. To estimate program impacts with increased statistical efficiency, regression models should be used. These models serve two goals: (1) they eliminate differences in outcomes between the treatment and control groups that may have occurred by chance as a result of differences in observed characteristics; and (2) they remove variation in outcomes due to observed characteristics, enabling us to detect statistically significant impact estimates with higher statistical efficiency. Successfully implementing an RCT design requires significant planning before implementation.

Quasi-Experimental Evaluations
When an RCT design is not feasible, quasi-experimental designs may be used to establish comparison groups to assess project impacts. In contrast to RCT evaluations, quasi-experimental evaluations are typically designed after the model has been initiated or, in some cases, once it has already been completed. Consequently, many quasi-experimental evaluations rely on baseline data collected by the agency that were designed for monitoring purposes, or as a proxy for measuring impact.

Depending on the data available it may be possible to conduct quasi-experimental evaluations using advanced statistical models to create credible comparisons that can detect and quantify program effects. In addition, using multiple methodologies to triangulate findings and document program impact may overcome the weaknesses of a single approach. In other cases, projects requiring quasi-experimental evaluation designs may lack baseline data to support impact evaluation goals. In such cases, a range of quantitative and qualitative designs should be considered based on available resources. Quasi-experimental designs rely on statistical methods.

Qualitative Research and Analysis
Qualitative research allows for the collection and analysis of in-depth information on individuals, groups, and communities—including social, political, organizational, and cultural factors that might not otherwise be captured. The following qualitative methodologies can be used as appropriate: in-depth interviews focus groups, ethnographies, and direct observation.

In-depth interviews are most appropriate when speaking with community and project leaders, and allow us to gain a detailed understanding of an individual’s thoughts and experiences. Focus groups are advantageous to interpret behavior as well as to learn about less understood topics and groups of
people. Ethnographies are another methodology that is useful to investigate behavior through real-world observations. Using this methodology, we are able to observe and understand the effects of a program on a community. Lastly, we can conduct direct observations of the community. This method is ideal for gaining a rapid assessment of behavior and the environmental factors or potential problems that need to be addressed immediately in an impact evaluation design. These data collection methods can be made more rigorous by the random selection of informants, for example, when using direct observation to collect data on health service provision. Qualitative analysis techniques include content, domain, and schema analysis.

**Content analysis** involves the systematic review and interpretation of qualitative data with the goal of identifying patterns, themes, biases, and meanings. Content analysis is most often applied to data collected through focus groups, interviews, and direct observation. In this method, themes are developed based on the topics the participants discuss as well as observations of environmental factors.

**Domain analysis** is a method of discovering semantic relationships between concepts in qualitative data, as well as discerning the social and cultural meanings that participants ascribe to those concepts. This approach is well-suited for unstructured data capturing where participants can assign their own importance to the concepts being discussed. Participants indicate the relationships that they believe exist between concepts; these relationships can be causal, rational, functional, or means-end.

**Schema analysis** examines patterns or themes in the language used by participants (especially in analogies and metaphors) to develop a mental model of the participants’ understanding of concepts. The relationships between concepts are mapped based on the choice of language that participants use in talking about those concepts. Similar word choices (such as similar analogies or metaphors) would indicate a similar understanding. This analytical technique could be applied to focus group data.

**Internal validity** is an original or single site test of a hypothesis that, using the best available methods, determines whether effects/impacts (final results) appeared in response to causes (activities, equipment, other interventions). Sometimes the original intervention is planned in advance as a test, often called a pilot. At other times, interest in replication and scaling up emerges when a project or program that was not set up as a test unexpectedly turns out to be more effective or successful than anticipated. Technically, what these two types of original interventions establish (or claims to have established) is called internal validity. Simply put, it means that the project/program intervention worked and produced the desired results.
Demonstrations
The ability to prove that a project works in one site does not mean that it will work everywhere. At the original site, there are an enormous number of situational characteristics, e.g., poverty levels, transportation system, political system, etc., as well as the organizational characteristics of the group that ran the project and the characteristics of the program/project beneficiaries. Altogether, this particular set of conditions will never exist in quite the same way elsewhere. In order to have confidence that a cause-and-effect model will work just as well in other localities or for other populations, researchers often conduct a second round of tests before trying to broadly scale up a project.

This second stage of testing is called a demonstration, and demonstrations of what worked at the original site are often carried out in several different sites at once, i.e., sites that differ from each other in ways that are important as determined by those associated with the original program/project. What second stage demonstrations test is external validity, i.e., does the model work effectively in a variety of circumstances. This second test is important. Even if the demonstration stage is only carried out in a few sites, it provides extremely important information, provided that demonstration sites differed from the original site in ways that may be important, i.e., that may interfere with success in the demonstration environments. For example, differences in literacy or poverty ranges between the pilot and demonstration sites could mean that fewer potential service users would be able to afford the program/project’s services or be able to reach labels and other critical materials.
Annex B: Scalability Assessment Tool, Terms, and Concepts

**Terms:**

**Model**: This refers to what is to be scaled up; however, it is not simply the original technical intervention. It is the slimmed down collection of all the inputs and processes both necessary and sufficient to achieve desired results in a variety of settings. Inputs include personnel, funding, and external support (popular and political). Processes include not only technical activities but administrative processes such as human resources, financial systems, and incentives to implement change.

**Concepts**

1. **Based on statistically significant, sound evidence of sizable impact.** This refers to scientific evidence. The more credible the evidence, the easier it is to convince policy and decision makers and other stakeholders of the value of the model. Statistically significant quantitative or qualitative evidence of impact is preferable. It is important to note that while impact data is more desirable than outcomes, and outcomes more desirable than outputs, etc., it is often the case that while pilots are constrained in proving impact so that “lower” levels of evidence are accepted, it is only acceptable if the logic connecting lower (outcomes) and higher (impact) levels is clear and confirmed by other studies or international evidence.

2. **Independent evaluation by respected and reliable sources.** Evidence from independent sources, such as an independent external evaluation, increases credibility. Often pilots rely on data conducted, collected, or analyzed by the organization itself, which even when of high-quality and good design, can be perceived as biased. For scaling up purposes, there is a strong preference for a formal external evaluation of the model. A second best alternative is the rigorous external review of internal evaluations combined with an external advisory panel in the design and implementation of the research design and monitoring and evaluation framework. Publication in a well-regarded peer-reviewed journal can usually be considered equivalent to an external evaluation or review.

3. **Model works in diverse social contexts.** A model works in diverse social contexts because it has been successfully implemented in multiple and diverse settings, or within a wider institutional context, such as access to and quality of services or commodities. Examples of relevant social variables might include population density, attitudes on family planning and
size, degree of poverty, and access to services, etc. Examples of relevant institutional variables are: availability of transportation, availability and cost of family planning commodities, and quality of care.

For the purposes of scaling up, there is a strong preference for projects that have been piloted in multiple sites and settings, i.e., that have both internal and external validity. This is particularly true in countries like India or Nigeria where even within national boundaries there is huge diversity in social norms, infrastructure, governance, incomes, etc. The following list combines measures of internal and external validity. The further up the ladder of success listed below, the stronger the candidate.

- Innovation (minimal objective evidence)
- Promising Practice (anecdotal reports)
- Model (positive evidence in a few cases)
- Good Practice (clear evidence from several cases)
- Best Practice (evidence of impact from multiple settings and meta-analyses)
- Policy Principle (proven, a “truism” essential for success)

4. The model is supported by eminent or credible individuals and institutions. Support or endorsements from eminent individuals or institutions help in advocacy efforts. These can be either recognized experts who confer legitimacy, e.g., the Indian College of Medical Research or the World Health Organization, or well-known and famous personalities who confer status, whether from the media, sports, politics, or other fields, e.g., first ladies, or the Indian actor/model Amitabh Bacchan’s support for polio vaccine.

5. The results are visible to casual observation; tangible. It is easier to convince people of the impact of things that they can easily see and experience for themselves then those they cannot. Experience has shown that it is easier to scale up interventions like bednets or treatments that stop maternal hemorrhage than those where the results are less visible or tangible, such as the empowerment of women or communities.

6. Results are clearly associated with the intervention. It is easier to convince people if the impact is not just a byproduct of an intervention, but easily attributable to the model itself. This criterion emphasizes the fact that decisions to adopt and implement models are often not made, or are only made, on the basis of objective, statistical evidence despite an increased emphasis on high-quality evidence and evidence-based policy making. Outcomes in health, education, or other fields are often driven by multiple factors. Skeptics may claim that the results observed were not due to the intervention but to other factors. While a good experimental or quasi-experimental design can address this for a technical audience, the ability to literally see the causal relationship can be an important factor for a non-technical audience. Models that are difficult to scale up are those in which impact is lagging or delayed or the causal mechanisms are not straightforward, e.g., the effects of psychosocial development on childhood performance. Counterexamples are Oral Rehydration Therapy
(salts) to reduce childhood diarrhea, an intervention with a direct, immediate, and simple causality. Sometimes models are able to go to scale, or at least convince key decision makers to approve adoption and funding, without strong evidence because their internal logic is inherently compelling; this is often true of models that involve training or have evidence from the literature. However it is often the case that there are several other assumptions which need to hold true for the causal chain to achieve desired outcomes, and it is important to test the validity of these assumptions.

7. **Evidence and documentation that have a strong emotional appeal exist.** This criterion emphasizes the fact that decisions to adopt and implement models are often not made on the basis of objective, statistical evidence but on emotions (despite the increased emphasis on high-quality evidence and evidence-based policy making). Seeing a sick baby healed or a woman who is bleeding to death revive and recover could be more important than dry statistical evidence to many policy and decision makers. Successful advocacy uses both scientific and other evidence to advance change, especially through stories, photos, video/film, and other media that are able to convey a message with an emotional appeal.

8. **Addresses an objectively significant, persistent issue.** It is easier to successfully advocate for social problems and issues when those issues affect large numbers of people in a significant way. In other words, it is easier to scale up models that an objective outside observer would rank as one of the major challenges in health, education, etc., for a country, population, or sub-region. In health, for example, this may be an issue that is a leading cause of death or recognized as an easily preventable or treatable cause of death or disease with permanent debilitating effects. That is why tuberculosis, malaria, and polio have all become major health priorities. In education, this may be levels of malnutrition and stunting in young children with the effect of permanent and destabilizing mental abilities. It is important to point out that just because an issue is objectively important, it does not mean that it is a major policy priority. One of the actions that can come out of a scalability assessment is precisely what needs to be done to move an objectively important issue higher up on the policy and social priority list. Early childhood education is a good example of an objectively important issue which, in many cases, has not received adequate attention.

9. **Addresses an issue that is currently a high (policy) priority of potential adopters and is aligned with organizational goals, mission, and vision.** This item is particularly relevant when scaling up is being considered by the government, where government approval, funding, or other roles may be important. When an issue is high on the policy agenda, it means that the government is actively looking for solutions and willing to provide funding. It is easier to scale up something which is already an important priority than to move something up the agenda. For example, a current environmental intervention that addresses maternal mortality is also a Millennium Development Goal; therefore, it is easier to scale up than interventions that address the health of gay, lesbian, bisexual, and transgender populations. It is a plus when organizations and their constituencies already consider the issue a high priority and when it is already aligned with the organization’s mission and vision; thus, expansion is facilitated when an organization’s funders or board of directors think the issue is important.
10. **Addresses a need sharply felt by potential beneficiaries or participants in the target area.** A felt need means that if survey research, focus groups, or other forms of interviews were conducted, the issue that the model addresses would emerge from participants as a major priority. It is easier to mobilize popular and grassroots support for interventions that address felt needs to achieve acceptance of new programs and interventions. Felt needs tend to be tangible and immediate like poverty and livelihoods, safe drinking water, and curative care as opposed to issues where benefits are captured in the future, e.g., preventive care, or where there lacks the perception that the status quo could or should be different, e.g., levels of infant or maternal mortality, or number of births per family.

11. **Current solutions for this issue are considered inadequate.** Current solutions refer to programs or policies already in place to address the issue. It is easier to advocate for the model if people and decision makers assess that the current solution is not working, or if there are no solutions at all. If there are no current solutions in place, this concept refers to whether people think the lack of a solution is a problem at all, e.g., providing child health interventions solely through facility-based approaches.

12. **Superior effectiveness to current solutions is clearly established.** This criterion should be self-evident. If the model being proposed for scale up has evidence of greater impact or effectiveness than existing solutions, it is easier to scale up.

13. **Superior effectiveness to other innovative models established.** Advocacy of a particular model or solution must compete with other approaches for the attention of policy makers. The model should be able to demonstrate success in achieving results, but also superiority over alternative approaches. It is also important to assess if there are any foreseeable potential opposition from vested interests or social/cultural groups. Some issues or solutions (the intervention) can threaten vested interests or become controversial for certain elements of the population. In public health, interventions which shift tasks from skilled to less-skilled professionals can threaten the former’s authority, prestige, and perhaps most importantly, livelihoods, even when they are already overburdened. For example, having VHWs in rural areas give injections of antibiotics to newborns with sepsis was opposed to by neonatologists, even though there was no evidence of complications in the administering of injections nor were there any neonatologists who actually served those populations. Similarly, (unqualified) rural medical practitioners have opposed the management of public primary health clinics by NGOs because they fear the loss of business if the quality of care, and therefore competition, improves. In many areas, adolescent sexuality and health education can be opposed by conservative social or religious groups on ethical or religious grounds. The lack of opposition can increase the prospects for scaling up. It is important to establish some clear standardized criteria for comparison with a common denominator, preferably in terms of outcomes and impacts.
14. **Implementable within existing organizational systems, infrastructure, and human resources.**
   It is easier to implement a model at scale if it can use existing systems, i.e., if they can be grafted on, then if they require the creation of a whole new infrastructure, organization, management, and systems. This is because investing in new systems and infrastructure is usually expensive and can be politically threatening to existing bureaucracies and organizations. However, on some occasions, creating a new system may have advantages in terms of circumventing political and bureaucratic obstacles and weak capabilities. Models which require long and intensive training periods for staff are more difficult to scale up and face opposition from potential adopters due to the costs and time involved.

15. **Contains a few components easily added on to existing systems.** The fewer the elements of a model, the simpler it is to scale up. The Home-Based Newborn Care model that was originally implemented had several distinct components which made large-scale implementers wary of scaling it up. Thus, while designing a scaling up strategy, it was important to simplify the model so that implementation on a larger scale was easier.

16. **Small departure from current practices and behaviors of the target population.** It is easier to implement a model if does not require significant changes from the existing behaviors, beliefs, and practices of the target population, clientele, or beneficiaries of the model, e.g., counseling mothers on using food cooked for the family as supplementary feeding for children, versus advocating the cooking of meals separately.

17. **Small departure from current practices and culture of the adopting organization(s).** This concerns the intervention’s compatibility with the culture, practices, physical infrastructure, and resources of the adopting organization(s). It is easier to implement a model if does not require significant changes from the existing behaviors, beliefs, and practices of the organization that will implement the model at scale. For example, in a government system that emphasizes delivery of curative medical services, the introduction of community mobilization, treating clients with respect and dignity, preventive services, or working with and through non-professional VHWs may require a substantial change in culture or norms. It is important to note that even in the case of Expansion, where the implementing organization remains the same, a major challenge may be in maintaining its organizational culture, practices, and roles as the organization grows. This criterion also assesses the extent to which adoption/scaling of the model is likely to meet internal opposition, resistance, or support within the adopting or expanding organization.

18. **Few decision makers are involved in agreeing to the adoption of the model.** This criterion addresses the number and hierarchy of decision makers required to approve scaling up. For example, the Home-Based Newborn Care model required not just the approval and buy-in of policy makers and programme implementers in the public health system, it also needed the approval of the Indian Academy of Paediatrics and the National Neonatology Forum. This process of engagement and negotiation with multiple decision makers can be tedious and slow the scaling up process.
19. **Demonstrated effectiveness in diverse organizational settings.** Compatibility with systems and infrastructure within diverse organizational settings is best demonstrated by actual evidence in those types of settings. This can help convince organizations and skeptics in general that the intervention will work, and serves as a strong counterweight to the “not invented here” argument—indicating that there is evidence that the model has had similar impact when implemented in multiple and diverse organizational settings whether it be a NGO, government, or private sector actor; or a tertiary, secondary, or primary facility in health. Diversity can refer to variances in quality in terms of infrastructure, equipment, supplies, and the effectiveness of the organization that is implementing the model. The more evidence available on the robustness and resilience of the model in different organizational settings, the easier it is to scale up.

20. **The model is not particularly value or process intensive.** Here, value or process are defined as models that focus on tacit knowledge, i.e., how things are done or delivered versus the technical content (which focuses on drugs, equipment, procedures, and information such as changing attitudes, knowledge, and practices). Value or process intensive models are much more difficult to implement at large-scale because: (a) quality is usually important, (b) they tend to be time and resource-intensive to transfer to others, and (c) are often a substantial departure from existing practices in organizations with large-scale capacity because they are difficult to systematize, relying heavily on organizational culture. Examples of values or process intensive components include: community participation, community mobilization, teaching service providers to treat beneficiaries with dignity or respect, and free play in early childhood education versus lectures and rote learning.

21. **Low technical sophistication of the components and activities of the model.** Models can be sophisticated or not whether they are technology/content-intensive or process intensive. The more sophisticated they are, the more they require either higher skilled and trained implementers or greater investments in the training and capacity building of personnel to implement them successfully. Thus, less sophisticated models are easier to scale. For example, standardized doses of drugs that require only one dose, do not require cold chains, are the same dosage regardless of body weight, and do not need monitoring of potential negative after effects are easier to scale up than those where multiple elements require a number of complex decision points.

22. **Key innovation is a clear and easily replicated technology.** A model which has a single element such as delivering a vaccine through an existing service delivery mechanism stands a much better chance of approval for scaling up. For instance, a childhood pentavalent vaccine was introduced only in states that had robust immunization programs, where it was perfected over several decades and easily scaled up with minimal modifications to the infrastructure and reporting mechanisms.
23. **Low complexity model, simple with few components added onto existing systems.** Models that are complex, have multiple elements, and need updated delivery mechanisms often require long lead-in times during which permission is obtained from gatekeepers and leaders, and acceptance and buy-in has to be created among participants, beneficiaries, and community leaders. In some cases, this can take a year or more; in other cases, it is not necessary because piloting organizations have already established trust and credibility based on their long-term relationships and presence in the localities in which they work. Regardless, models which require the building of trust, relationships, and permission from gatekeepers are harder to scale up or at least, take much longer. Models vary widely in terms not only of the pre-conditions necessary before a model is implemented, but the training, skills building, and general capacity required of front-line implementers, supervisors, and other staff. Capacity building is time, effort, and resource-intensive and often difficult to replicate at scale when all three of these elements are scarce.

24. **Model requires little supervision or monitoring.** Models which require intensive monitoring and supervision are harder to scale up. Many organizations with large capacity are weak in these areas, and it can be difficult to enforce monitoring and supervision at large-scale. Models in which implementers are either self-motivate or where they can work effectively independently are easier to scale up. Monitoring intensive models can be made simpler by the use of monetary and non-monetary incentives, and by using electronic data collection systems supported by on site supervision as required.

25. **Able to be tested by users on a limited scale.** This means that organizations that are interested in adopting the model should be able to run their own pilots without having to commit substantial resources or undergo significant organizational changes to see if it works.

26. **Superior cost-effectiveness to existing and competing solutions clearly established.** Models not only need to be more effective than existing or competing solutions to have a chance of being scaled up, they need to be more cost-effective. This requires getting comparable measures of cost-effectiveness, which can be hard to come by in low-resource situations.

27. **Requires a large commitment of funds at scale.** Models that require substantial upfront commitments are generally complex and require changes in existing systems. Advocacy for this is facilitated by demonstrating high impact, extensive stakeholder support, and importantly, a good understanding of the unit cost (or some other measure of impact) per resources spent. This needs to go beyond simple calculations such as the total project budget divided by the number of beneficiaries, communities, etc., which often underestimates costs by ignoring the contributions of management and technical assistance or which overestimates them by including evaluation costs which will not be replicated at scale. Having solid cost data is necessary for successful advocacy, and knowing whether or not an intervention is affordable given the available resources and objective need can make or break an intervention in terms of scalability.
The model has its own internal funding (e.g., user fees), corpus or endowment, or some other long-term sustainable funding source, or overall funding for this sector is a priority. Funding here refers to the funding of the model and not the project which piloted the model. It means that the model includes an internal mechanism of recovering costs whether they are user fees, profit margins on goods or services provided, etc. Overall funding for this sector is a priority and growing, to the extent that there are unspent funds. Funding refers to public sector support for the general sector in which the model works, e.g., health, education, livelihoods, poverty, or women and children. When thinking about this issue, it is worth considering if there are alternative sources of funding.

Annex C: Field Applications of SUM Framework

India
1. Home-based neonatal care (Society for Action and Research in Health)
2. Improving immunization coverage through incentives (Seva Mandir)
3. Training of primary medical officers in emergency obstetric care (Federation of Obstetrics and Gynecology)
4. Using community networks and local governments for improved health and nutrition (Community Health Care Management Initiative)
5. Management of public health facilities by NGOs (Karuna Trust)
6. Cashless hospital services through micro insurance (Self-Employed Women’s Association)
7. Promoting adolescent friendly health services through schools and communities in an urban setting (Sangath)
8. Reproductive health of married adolescent girls in rural settings (Institute of Health Management, Pachod)
9. Provision of family planning services using social franchisee clinics (Janani)
10. Increasing contraceptive use among newly married couples (Pathfinder)
11. Promoting reproductive health awareness among tribal youth (RISHTA, Tata Steel Rural Development Services)
12. Involving elected women’s representatives in improving adolescent reproductive and sexual health services (CEDPA)
13. School-based delivery of adolescent reproductive and sexual health services (CEDPA)
14. Early childhood development through integrated child development services (ICDS)
15. Comprehensive abortion care in government health facilities (IPAS)
16. Community health workers as social mobilizers and service providers (The Mitanin Programme)

Nigeria
17. Holistic, community-based approach to health education (Community Life Project)
18. Maternal mortality and morbidity (Pathfinder)
19. Non-pneumatic anti-shock garment (University of Ibadan/U.C. San Francisco)

Mexico
20. Community-based maternal and childcare services (MexFam)
21. Public-private partnership for improved policies, training materials, and training of trainers in sexual education (Government of Mexico/NGO consortium)
22. Targeted sexual education curriculum for Indian populations (University, Government, NGO consortium)
Founded in 1981, MSI is an 800-person international development consulting firm located in Washington, DC, and serving clients worldwide. MSI provides management consulting services to governments, local organizations, foundations, corporations and international donor agencies in more than 50 countries. In 2008, MSI was acquired by Coffey International and now forms part of the Coffey family with offices in 14 countries around the world.
